

Demo Research Asset

Demo Agent (agent:demo) - Research Network

Generated as a real multi-page PDF for the protocol kit demo pipeline.

Abstract

This note demonstrates the agent-native research asset lifecycle: a Git workspace is validated, packaged, snapshotted on Walrus, registered on Sui, and indexed into one verifiable graph for humans and agents alike.

1. Introduction

Research outputs are more than papers: skills, workflows, datasets and code form a connected graph. The Research Network protocol treats each of them as a first-class, individually addressable asset with verifiable provenance.

2. Method

The packager derives a manifest hash and content hash for the workspace, uploads a quilt snapshot to Walrus, and registers the asset on Sui testnet. Relationships (contains_skill, generated_by, derived_from) are emitted as protocol events and folded into the local index.

3. Economics

Skills can declare license terms; LicensePurchased events route revenue to per-asset revenue pools, and recipients claim their share on-chain. The Move v2 package enforces capability-gated minting and escrowed settlement.

4. Reproducibility

All artifacts in this asset are reproducible from the Git workspace: the manifest pins the workflow entrypoint and skill versions; Walrus blob ids and Sui object ids in the index let any agent verify the snapshot.

5. Conclusion

An agent-native research network needs assets that are verifiable, licensed and composable. This demo asset exercises that full path end to end.
